ABSTRACT

Today's internet technology is not free from many problems or security

holes. This security hole could be exploited by an unauthorized person to steal

important data. The case of the attacks occurred because the party that was

attacked also did not realize the importance of network security to be applied to

the system.

Honeypot is a system that is designed to resemble the original production

system and is made with the intention to be attacked / compromised. Honeypot

implemented using high interaction honeypot as well as using other supporting

software. Durability test conducted with direct attacks to determine the safety of

the system.

This attack was made with five ways to use brute force directiory buster,

RFI, SQL Inject, strest test and DoS. Honeypot can simulate the attack very well,

but not with DoS attacks. So the honeypot is able to fool the hacker being able to

provide a good response from the attack.

Keywords: honeypot, high interaction, web server, security.
