

ABSTRACT

A deposit service is an activity carried out by someone who is traveling to a place and entrusts the services of buying goods based on the wishes of the person who entrusts. Moreover, the enthusiasm of the Indonesian people to take a vacation in the country and abroad is increasing. Based on the results of the survey, 86% of Indonesians surveyed stated that they prefer to vacation in the country, while 14% choose to vacation abroad. Therefore, these moments become an opportunity to open business services for entrusted services between people who are traveling (Personal Shopper) with people who are entrusting (requester). Along with the development of time, the deposit service process continues to develop, therefore, we need a platform that can help in entrusting transaction services.

Based on the survey conducted at this time as many as 57.6% of people who do entrust services still use social networks such as Instagram as a promotional media, and as much as 39% use verbally in conducting promotions. When entrusted services use Instagram the information provided is only limited to existing followers, meaning that people who do not follow the account do not know information about the entrusted services. Because we need a platform that can connect between people who are travelling (personal shopper) with people who are not married who want to buy goods and do not want to get out of the house (requester). Leave Time can be an application service solution to help these problems. Period time is an application that connects people who are not married to people who travel domestically or internationally.

This application can be accessed using a web browser because this application is web-based so devices that can be used are smartphones, iPhone and laptops. This application development uses the PHP programming language and laravel framework. Features that will be developed in the Time Leave application are account management, trip management, transaction management, shopping account management, item delivery management, admin management. The method used in developing this application is the iterative incremental method. This method is used because user needs are always evolving and changing, so this method is suitable because the system development is gradual and repetitive. The stages of application development include the phase of inception, elaboration, construction and transition

Keywords: Personal Shopper, requester, entrusted service, web application
